Why don't macroinvertebrates recover in urban restored streams?

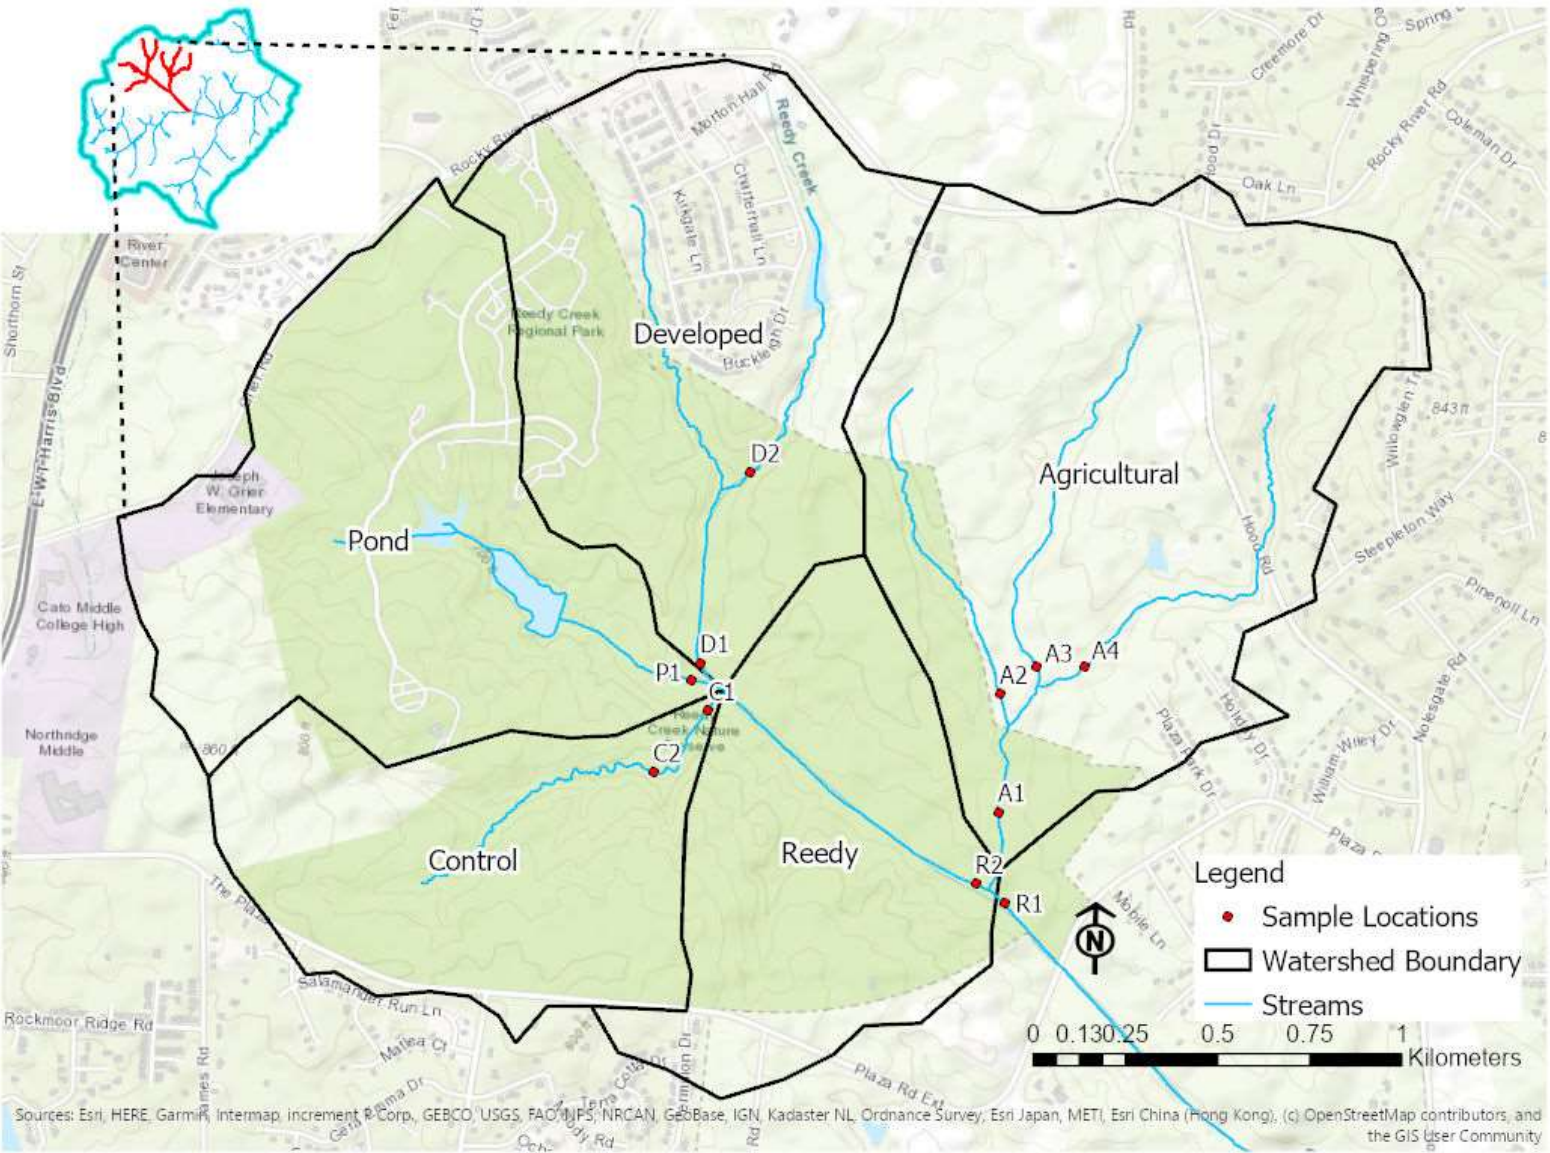

- Small scale of projects (< 2 km)
- Stormwater inputs upstream
- Disruption of food sources
- Lack of colonists

Reedy Creek Restoration Project

- Large scale restoration project
- Primarily forested
- “Excellent” (NCBI) <2 km from restored sites

Site	Area (km ²)
D2	0.27
D1	1.15

Methods

- **11 sites sampled seasonally Fall 2012 – Summer 2020**
- Modified NC Qual 4 (no kick net)
- Samples placed in 90% ethanol in the field and 70% ethanol in the lab
- Taxa identified to lowest taxonomic level possible
 - Chironomidae (TV =7)
- **Metrics calculated**
 - Taxa richness
 - EPT richness
 - NCBI score

Questions:

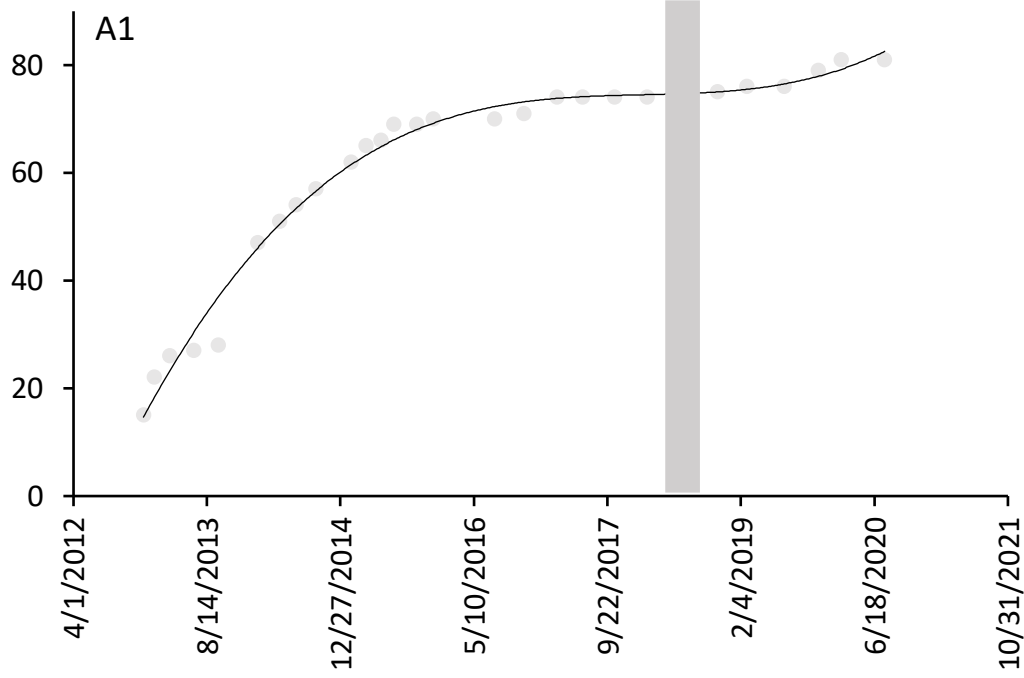

- 1. How quickly are new taxa added and how does this recovery relate to land use?**
2. How do key metrics (richness, NCBI) change pre/post restoration? How do these metrics and recovery vary across land use?
3. How does restoration impact the community (all taxa and EPT) pre/post restoration?

Increase in number of taxa 2 y post-restoration

Number of Cumulative Taxa

Lesson #1: It is challenging to determine if we added new taxa post-restoration

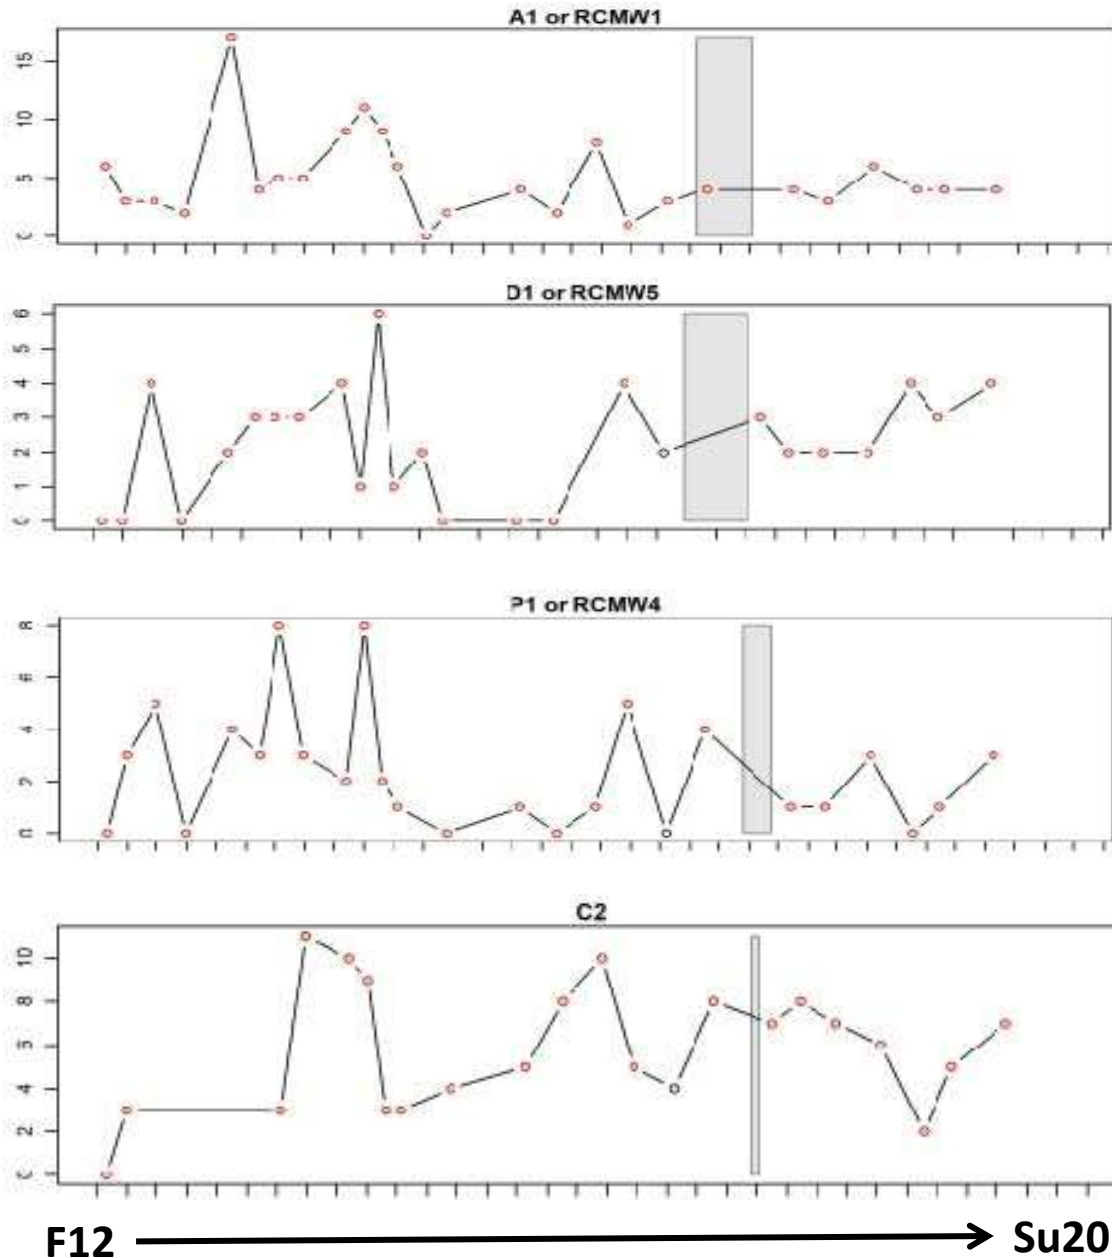

- Important to have pre-restoration data
- Rate of taxon detection varies between “good” versus “poor” sites
- Adding 1-2 taxa/year after >10 years in local monitoring programs
- Restoration studies often comparing to “good” sites but not all sites are monitored for decades

Questions:

1. How quickly are new taxa added and how does this recovery relate to land use?
- 2. How do key metrics (richness, NCBI) change pre/post restoration? How do these metrics and recovery vary across land use?**
3. How does restoration impact the community (all taxa and EPT) pre/post restoration?

Key Metrics – Pre and Post Restoration

We have 2 years post-restoration data

Compare 2 yrs pre with 2 yrs post

- t-test
- **Mann-Whitney test**

Before-After-Control-Impact (BACI)

- Before = Pre
- After = Post
- Control = C2 unrestored
- I = all other sites

	Pre C2	Pre A1	Post C2	Post A1	Diff Pre	Diff Post
Date 1	26	28	58	188	-2	-130
Date 2	56	5	68	84	51	-16

Number of sites scored “excellent” decrease post-restoration

Lesson #2: Metrics may not capture changes post-restoration

- Metrics based on richness are impacted by which taxon are added
- Metrics based on abundance may not respond if the taxon being added is rare
- Metrics vary seasonally and yearly so long-term data may be needed to see changes

Questions:

1. How quickly are new taxa added and how does this recovery relate to land use?
2. How do key metrics (richness, NCBI) change pre/post restoration? How do these metrics and recovery vary across land use?
3. **How does restoration impact the community (all taxa and EPT) pre/post restoration?**

There has been an assemblage shift from pre- to 2 y post-restoration

Lesson #3: Community changes are important

- While metrics were not significant we did see changes in the percent composition of the community
 - Decrease in stoneflies but increase in caddisflies post-restoration
- Multivariate analysis indicates that there are different communities pre- and post-restoration
 - Can look at individual taxa to see what is driving these changes
- Need to look at function (long lived species, functional feeding groups)

Overall Summary

- Incredibly rich dataset with a long pre-restoration period
- Differences in how subwatersheds are responding post-restoration
- Challenging to know if we are adding “new” taxa given number of rare taxa still being discovered
- Taxa and EPT richness increased at the worst sites but decreased at the better sites
- 2 y post-restoration there has been a shift in the community across the watershed
